Received October 27, 2013; Revised December 08, 2013; Accepted December 24, 2013

Abstract Cancer is one of the leading causes of death and globally the numbers of cases of cancer are increasing gradually. There are several medicines available in the market to treat the various types of cancer but no drug is found to be fully effective and safe. The major problem in the cancer chemotherapy is the toxicity of the established drugs. However, plants and plant derived products have proved effective and safe in the treatment and management of cancers. These days most of the research work on cancer drugs is targeted on plants and plants derived natural products. Many natural products and their analogues have been identified as potent anti-cancer agents and day by day the anti-cancer property of various plants is being identified. Here an attempt is being made through this review to highlights the natural products and their analogues established as anti-cancer agents and the new plant species identified with anti-cancer properties either in vivo or in vitro.

Keywords: cancer cells, natural products, plants, carcinoma

Cite This Article: Om Prakash, Amit Kumar, Pawan Kumar, and Ajeet, “Anticancer Potential of Plants and Natural Products: A Review.” American Journal of Pharmacological Sciences 1, no. 6 (2013): 104-115. doi: 10.12691/ajps-1-6-1.

1. Introduction

Cancer is a major public health burden in both developed and developing countries. It is an abnormal growth of cells in body that can lead to death. Cancer cells usually invade and destroy normal cells. These cells are born due to imbalance in the body and by correcting this imbalance, the cancer may be treated. Billions of dollars have been spent on cancer research and yet we do not understand exactly what cancer is. Every year, millions of people are diagnosed with cancer, leading to death. According to the American Cancer Society, deaths arising from cancer constitute 2–3% of the annual deaths recorded worldwide. Thus cancer kills about 3500 million people annually all over the world. Several chemo preventive agents are used to treat cancer, but they cause toxicity that restricts their usage.

1.1. What Causes Cancer?

Cancer begins with mutations in DNA, which instructs the cells how to grow and divide. Normal cells have the ability to repair most of the mutations in their DNA, but the mutation which is not repaired and causing the cells to grow becomes cancerous [1].

1.2. Environmental Factors

Environmental factors which, from a scientist’s standpoint, include smoking, diet, and infectious diseases as well as chemicals and radiation in our homes and workplace along with trace levels of pollutants in food, drinking water and in air. Other factors which are more likely to affect are tobacco use, unhealthy diet, not enough physical activity, however the degree of risk from pollutants depends on the concentration, intensity and exposure. The cancer risk becomes highly increased where workers are exposed to ionizing radiation, carcinomas chemicals, certain metals and some other specific substances even exposed at low levels. Passive tobacco smoke manifold increase the risk in a large population who do not smoke but exposed to exhaled smoke of smokers [1].

1.3. Ayurvedic Concept of Cancer

Charaka and Sushruta Samhita [2,3] both described the equivalent of cancer as “granthi” and “arbuda” [4]. “Granthi” and “Arbuda” can be inflammatory or devoid of inflammation, based on the doshas involved [5]. Three doshas “Vata, Pitta and Kapha” in body are responsible for disease and the balanced coordination of these doshas in body, mind and consciousness is the Ayurvedic definition of health [6]. Tridoshicarbudas are usually malignant because all three major body humors lose mutual coordination, resulting in a morbid condition [7]. Neoplasm can be classified in Ayurveda depends upon various clinical symptoms in relation to tridoshas.

Group 1: Diseases that can be named as clear malignancies, including arbuda and granthi, such as mamsarbuda (sarcomas) and raktarbuda (leukaemia), mukharbuda (oral cancer), and asadhya vrana (incurable or malignant ulcers).
Group II: Diseases that are not cancers but can be considered probable malignancies, such as ulcers and growths. Examples of these are mamsaja osatharoga (growth of lips), asadhya galganda (incurable thyroid tumour), tridosaja gulmas, and asadhya udara roga, (abdominal tumours like carcinomas of the stomach and liver or lymphomas).

Group III: Diseases in which there is a possibility of malignancy, such as visarpa, asadhya kamala (incurable jaundice), asadhya pradara (intreatable sinusitis).

2. Role of Plants As Medicinal and Anti-Cancer Agents

Plants, since ancient time, are using for health benefits by all cultures as well as source of medicines. It has been estimated that about 80-85% of global population rely on traditional medicines for their primarily health care needs and it is assumed that a major part of traditional therapy involves the use of plant extracts or their active principles [8,9,10]. Although a lot of recent investigations have been carried out for advancements in the treatment and control of cancer progression, significant work and room for improvement remain. The main disadvantages of synthetic drugs are the associated side effects. However natural therapies, such as the use of the plants or plant derived natural products are being beneficial to combat cancer. The search for anti-cancer agents from plant sources started in the 1950s when discovery and development of the vinca alkaloids (vinblastin and vincristine), and the plant was originally endemic to Madagascar, but the samples used in the discovery of vincristine and vinblastine were collected in Philippines and theJamaica. Recently semi-synthetic analogues of vinca alkaloids are vinorelbine (VRLB) and vindesine (VDS). These are primarily using alone or in combination with other chemotherapeutic drugs to combat a variety of cancers. VLB is using for the treatment of lymphomas, leukemias, breast cancer, testicular cancer, lung cancers, and Kaposi’s sarcoma. VCR also showed efficacy against leukemia, particularly acute lymphocytic leukemia in childhood. Of over 2069 anti-cancer clinical trials recorded by the National Cancer Institute as being in progress as of July 2004, over 160 are drug combinations including these agents against a range of cancers [12].

3.2. Podophyllotoxin Derivatives

The species of Podophyllaceae family such as Podophyllum peltatum Linn., P. emodi Wallich have been reported with a long history of therapeutic use, including the treatment of skin cancers and warts. Podophyllum peltatum have been used by the Native Americans for the treatment of “cancer”. The interest was promoted by the observation in the 1940s that an alcohol extract of the dried roots (called podophyllin) cures venereal warts by topical application. The chief cytotoxic therapeutic constituents were identified as podophyllotoxins and have been first isolated in 1880, but its correct structure could only be elucidated in the 1950s with the advancement in spectroscopic techniques. Other closely related podophyllotoxins like lignans were also isolated during this period and became introduced into clinical trials, but they were dropped due to lack of efficacy and unacceptable toxicity. Extensive research studies at Sandoz Laboratories in Switzerland in the 1960s and 1970s led to the development of etoposide and teniposide as clinical agents which are being used in the treatment of lymphomas and bronchial and testicular cancers. Of 2069 anti-cancer clinical trials recorded by the NCI as being in progress as of July 2004, over 150 are drug combinations including etoposide against a range of cancers [13].

3.3. Taxanes

A more recent advancement in the development of plant-derived chemotherapeutic agents is the development of a class of molecules called taxanes. Paclitaxel also named as taxol was first isolated from the bark of Taxus brevifolia Nutt. (Taxaceae). The use of various parts of T. brevifolia and other Taxus species (e.g. T. canadensis Marshall, T. baccata L.) by several Native American tribes for the treatment of some non-cancerous conditions has been documented, while the leaves of T. baccata are used in the Ayurveda, with one reported use in the treatment of “cancer”. Paclitaxel biosynthesizes and occurs in the leaves of various Taxus species, and the ready semi-synthetic conversion of the relatively abundant baccatin to paclitaxel, as well as active paclitaxel analogs, such as docetaxel (Taxotere), has provided a major, renewable natural source of this important class of drugs. Paclitaxel is used in the treatment of wide variety of cancers including breast, ovarian and non-small-cell lung cancer, and has also shown efficacy against Kaposi sarcoma. It has also attracted attention due to its potential in the treatment of psoriasis, multiple sclerosis, and rheumatoid arthritis. Docetaxel, a semisynthetic derivative, is primarily used in the treatment of breast cancer. The importance of this class of anti-cancer agents can be evaluate by the fact that more than one dozen taxanes analogues are in clinical or preclinical development. In addition, of 2069 cancer clinical trials recorded by the NCI as being in progress as of July 2004, 248 are listed as involving taxane-derived drugs, including 134 with paclitaxel (Taxol), 105 with docetaxel (Taxotere), and 10 with miscellaneous taxanes, either as single agents or in...
combination with other anti-cancer agents. In addition, 23
taxanes are in preclinical development [14].

3.4. Camptothecin Derivatives

Another advancement that was made in the anti-cancer
drug is the class of clinically-active agents derived from
camptothecin. Camptothecin was first isolated from the
Chinese ornamental tree, *Camptotheca acuminata* Decne
(Nyssaceae), and known in China as the tree of joy. The
extract of *C. acuminata* was the only extract out of 1000
various plant extracts tested for anti-tumor activity which
showed efficacy, and the active constituents isolated was
identified as camptothecin. Camptothecin was introduced
to clinical trials by the National Cancer Institute in the
1970s, but withdrawn soon because of reports of severe
bladder toxicity. Extensive researches performed by
several organizations for a search of more effective
camptothecin derivatives and Topotecan (Hycaatin) was
developed by SmithKline Beecham (now Glaxo
SmithKline), and Irinotecan was developed by the
Japanese company, Yakult Honsha, are now in clinical use.
Topotecan is used for the treatment of ovarian and small-
cell lung cancers, while Irinotecan is used for the
treatment of colorectal cancers. Of the 2069 cancer
clinical trials recorded by the NCI as being in progress, as
of July 2004, 94 or approximately 4.5% are listed as
involving camptothecin-derived drugs, including 64 with
irinotecan (CPT-11), 26 with topotecan, and 4 with other
miscellaneous analogues, either as single agents or in
combination with other anti-cancer agents. In addition, 15
other camptothecin derivatives are in preclinical
development [15].

Figure 1. Structures of Plant-Derived Anti-Cancer Agents in Clinical Use

3.5. Homoharringtonine

Other plant-derived agents, which are in clinical use, are
homoharringtonine. Homoharringtonine was originally
isolated from the Chinese tree *Cephalotaxus harringtonia*
var. *drupacea* (Cephalotaxaceae). Elliptinium was isolated
from species of several genera of the Apocynaceae
family including *Bleekeria vitensis*, a Fijian medicinal plant
with reputed anti-cancer properties. A racemic mixture of
harringtonine and homoharringtonine (HHT) is being used
successfully in China to combat acute myelogenous
leukemia and chronic myelogenous leukemia. Purified
homoharringtonine has shown efficacy against various
leukemias, including some resistant to standard treatment,
and has been reported to produce complete hematologic
remission in patients with late chronic phase chronic
myelogenous leukemia. Elliptinium is marketed in France
for the treatment of breast cancer [16].

4. Plants Proved Effective As Anti-cancer Agent in vivo or in vitro

4.1. Achyranthes Aspera

*Achyranthes aspera* Linn. (Family-Amaranthaceae) is a
commonly found herb as a weed on road sides throughout
India. The methanol extract of *Achyranthes aspera*, its
alkaloid, non-alkaloid and sapogenin fractions has been
exhibited significant inhibitory effects on the Epstein-Barr
virus early antigen activation induced by the carcinoxin
12-O-tetradecanoylphorbol-13-acetate in Raji cells (at a
concentration of 100µg). In *in vitro* study the non-
alkaloid fraction containing mainly nonpolar compounds showed
the most significant inhibitory activity [17]. In *in vivo*
two-stage mouse skin carcinogenesis test the total methanol
extract possessed a pronounced cytotoxic activity [18].

4.2. Allium Sativum (Allicin)

*Allium sativum* (garlic, lasun) is used to treat a wide
variety of diseases in India. Allicin is a major component
of raw garlic and ajoene is a product of the rearrangement
of allicin. Its cytotoxic effect has been tested using human
primary fibroblasts, a permanent, nontumorgenic cell line
derived from baby hamster kidney cells and a tumorgenic
lymphoid cell line derived from a Burkitt lymphoma. The
cytotoxic action was in the range 2-50 µg/ml [19]. Some
organo-sulfur compounds from garlic, like S-allylcysteine,
are reported to retard the growth of chemically induced
and transplantable tumors in several animal models [20].
Administration of garlic (250 mg/kg, p.o., thrice a week)
in male wistar rats, has been significantly suppressed 4-
nitroquinoline-1-oxide induced tongue carcinogenesis as
revealed by the absence by the carcinomas in the initiation phase and their reduced incidence in the post initiation phase [21]. Thus the consumption of garlic may beneficial providing some kind of protection from cancer.

4.3. Andrographis Paniculata

Phytochemical investigation of the ethanol extract of the aerial parts of *Andrographis paniculata* has been reported the isolation of 14 compounds; a majority of them are flavonoids and labdane diterpenoids. The cytotoxic activities of these compounds have been evaluated against various cell lines and found that these isolates have a potent tumour inhibitory activity against all investigated cell lines [22]. The methanol extract of *Andrographis paniculata* was fractionated, dichloromethane fraction reported to possess three active constituents which were further tested and exhibited cytotoxic activity and also potent immunostimulating activity [23]. However, there were also its adverse side effects were also reported which may include gastric upset, headache, bitter taste and fatigue. High doses of *Andrographis paniculata* may have affect the normal functions of liver [24].

4.4. Annona Muricata

Graviola is known by its scientific name, *Annona muricata*. The important class of medicinal components found in graviola is acetogenins. Acetogenins was found in the fruit, seeds, leaves, and bark of the graviola plant. Preliminary research showed that acetogenins block production of adenosine triphosphate, which inhibits the pump that removes cancer drugs from the cell, allowing chemotherapy to be more effective. Furthermore, research suggested that acetogenin may have chemotherapeutic potential, especially against cancer that resistant to multiple drugs [25]. Parkinson like symptoms can occur on oral ingestion of graviola [26]. Some specific acetogenins have been reportedly identified to be toxic for various cancer cell lines like lung solid human-breast cancer, tumor carcinoma, pancreatic carcinoma, prostatic adenocarcinoma, colonic adenocarcinoma, human lymphoma, liver cancer, and multiple-drug resistant human-breast adenocarcinoma [27].

4.5. Apis Mellifera

*Apis mellifera* is the scientific name of honey bee, from which honey is produced. Honey is used to hasten healing of skin wounds, ulcerations, and burns in Indian system of medicine. A protein of the honeybee *Apis mellifera* has been reported to enhance proliferation of primary-cultured rat hepatocytes and also suppresses apoptosis [28]. It has also showed cytotoxicity in normal human lymphocytes and HL-60 cells [29]. Hamzaoglu et al. (2000) implantan cancer cell into neck wounds of mice, then divided mice into two groups. A significant decrease in wound cancer tumors were observed in the groups of mice that were treated with surgical wounds coated with honey pre and postoperatively. This finding may have some application in human surgery [30].

4.6. Astragalus Hedysarum

A polysaccharide from *Astragalus hedysarum* has shown anti tumor activity. An intraperitoneal injection of 500 mg/kg resulted in increase in the deposition of the third component of complement (C3) of macrophages in ICR mouse after two hours. The injection of *Astragalus hedysarum*, when given five times, the proportion of C3 positive macrophages was more than that of one time injection. The results suggest that *Astragalus hedysarum* has immuno-potentiating action and can be useful in cancer chemotherapy [31]. Other species of *Astragalus* like *A. membranaceus* has also been investigated for its cytotoxic activity. *Astragalus membranaceus*, has been shown to be capable of restoring the impaired T cell functions in cancer patients [32]. *A. membranaceus* was reported to induce monocyte differentiation of human and murine cells in vitro. The studies showed that *A. membranaceus* exhibited in vitro and in vivo anti-tumor effects, which might be linked with activating the anti-tumor immune mechanism of the host [33].

4.7. Bidens Pilosa

*Bidens pilosa* is a folk medicine reported with the presence of polyacetylenes, flavonoids, terpenoids, phenylpropanoids and others. An extensive research work on different extracts of *Bidens pilosa* and further fractionation led to the isolation and characterization of potential marker compound phenyl-1,3,5-heptatriyne. This marker compounds revealed the toxicity profile on normal blood cells in erythrocyte osmotic fragility experiments along with other extracts [34]. Hexane, chloroform and methanol extracts of *Bidens pilosa* and their fractions were tested on various cancer cell lines. Results exhibited the antitumor activity of extracts among which hexane extract pronounced the most remarkable activity [35].

4.8. Bolbostemma Paniculatum

Extraction and further fractionation of chinese herb *Bolbostemma paniculatum* (Cucurbitaceae) led to the isolation and characterization of a triterpenoid saponin Tubeimoside-V. Further investigations on tubeimoside-V revealed the apoptotic killing nature on glioblastoma cells, thus suggesting its critical role in antitumor chemotherapy [36]. Other tubeimosides like tubeimodes-I, tubeimodes-II and tubeimoside-II also exhibited promised cytotoxic activity which may be linked to the inhibition of DNA synthesis and may induce phenotypic reverse transformation of tumor cells [37].

4.9. Cannabis Sativa

*In vitro* studies of components of marijuana (*Cannabis sativa*) indicate a potential to inhibit human breast cancer cells and to produce tumor eradications. In experiments introducing marijuana to malignant brain tumors, it was found that survival of animals was increased significantly [38]. The active components of *Cannabis sativa* are cannabinoids. Cannabinoids and their derivatives exert palliative effects in cancer patients by preventing nausea, vomiting and pain and also stimulated the appetite. These compounds have also been shown anti-tumor activity in cell culture and animal models by modulating key cell-signalling pathways [39].
4.10. Centaurea Ainetensis
The cytotoxic activity of *Centaurea ainetensis* extracts has been studied in human colon carcinoma cells. The crude extract of *Centaurea ainetensis* inhibited the proliferation of a host of colon-derived cancer cells. In *vivo* the crude extract, administered intraperitoneally before administration of subcutaneous injection of 1,2-dimethylhydrazine (a potent carcinogen), reduced the number of tumors and also decreased the mean size of abberant crypt foci. Further fractionation studies of the crude extract resulted in the isolation and characterization of bioactive sesquiterpene Lactone molecule called Salograviolide-A, which decreased the growth in inhibition in colon cancer cell lines when administered to normal human intestinal cells. Salograviolide A also exhibited potent cytotoxic action against epidermal squamous cell carcinogenesis [40,41].

4.11. Camellia Sinensis (Green Tea)
Epigallocatechin-3-gallate (EGCG) is the most abundant polyphenol in green tea. Some epidemiological studies revealed that EGCG can inhibit the invasion and migration of human colon and oral cancer cells. The effects of EGCG may be partially linked with the decreased productions of MMP-2, MMP-9 and uPA [42]. It was also observed that EGCG inhibit the growth of cancer cell lines like hepatocellular carcinoma through induction of cell cycle arrest [43]. EGCG was also inhibited the growth of cancer cells in ovarian carcinoma cell lines HEY and OVCA, in human colon and rectal cancer cell lines HT-29 and HCA-7 [44-46,47]. Apart from EGCG other flavonoids such as rutin, quercetin also inhibited the growth of cancer cell lines like HT-29 and HCA-7 [44,45,46,47]. It was also observed that EGCG inhibit the growth of colon cancer cell lines at non-cytotoxic concentrations when administered to normal human intestinal cells. Salograviolide A also exhibited potent cytotoxic action against epidermal squamous cell carcinogenesis [40,41].

4.12. Daphne Mezereum
*Daphne mezereum* is a plant widely used as a folklore remedy for treating cancer like symptoms. A hydro alcohol extract of *Daphne mezereum* has exhibited a potent antileukemic activity against lymphocytic leukemia in mice. Further fractionation studies on the extract resulted in the isolation and characterization of mezerein as a potent antileukemic compound [49].

4.13. Gossypium Hirsutum
*Gossypium hirsutum* or *Gossypium herbaceum* also called as Gossypol or cottonseed oil and used as a male contraceptive, in the treatment of metastatic carcinoma of endometrium or ovary and also used in HIV. Some *in vivo* and *in vitro* studies revealed the antitumor properties of gossypol on many cytotoxic and mitochondrial enzyme systems that is fundamental for tumor cell growth, including melanoma, endometrial, colon, lung, prostate, breast, brain, and adrenocortical cancer [50,51,52]. However no typical dose is yet suggested for the treatment of cancer and self-medication with gossypol is not safe because of its potential toxicity [53].

4.14. Hydrocotyle Asiatica
*Hydrocotyle asiatica* is the scientific name of Gotu kola, brahmi, synonyms with *Centella asiatica*. In early studies on animal tissue, brahmi exhibited cytotoxic and antitumor properties. It has been found that brahmi increased the life-span of tumor-bearing mice. Brahmi usually is tolerated well when used in typical doses of 600 mg of dried leaves three times a day [54]. A side effect is photosensitiveness; therefore, individuals using brahmi are advised to wear sunscreen and clothing to prevent sunburn [55]. An aqueous extract of leaves of brahmi has shown prominent cytotoxic activity against mouse melanoma, human breast cancer, rat glioma cell lines [56]. *C. asiatica* crude extract and its purified fractions has slowed down the development of solid and ascites tumors, also prolonged the life span of tumors bearing mice. Cytotoxic and antitumour effect involves direct action on DNA synthesis [57]. *C. asiatica* modulate nitric oxide and tumour necrosis factor-alpha in mouse macrophages [58]. Asiaticoside was found possessing prominent wound healing activity which may be associated with its effect on collagen synthesis. As asiaticoside induce apoptosis and enhance antitumor activity when administered with vincristine, it may be useful in cancer chemotherapy [59]. Asiatic acid was also found having anticancer effect on skin cancer [60].

4.15. Hypericum Perforatum
Hypericin is the active constituent which was isolated and characterized from *Hypericum perforatum*, also called as St John’s Wort. Naphthodianthrones are the group of compounds which belong to hypericin. Hypericin reduced and retarded the glioma cell lines growth *in vitro* and also induced death of glioma cell which was linked to inhibition of Protein Kinase-C, as measured by thymidine uptake. The hypericin’s activity to inhibit glioma cells was comparable or greater than tamoxifen which was used as reference standard [61,62]. *Hypericum perforatum* inhibitory activity was due to its components, which inhibits serotonin reuptake and thus reduces cell growth on several cancer cell lines, *in vitro* and *in vivo* [63].

4.16. Mangifera Indica
*Mangifera indica* is a nutritional supplement used in several tribes and countries as a folklore remedy. This aqueous extract is considered in Cuba beneficial and used in healthy people to reduce environmental, nutritional risk factors, and also prolong the quality of life through increasing free radical scavenging mechanism [64]. Ethno-botanical studies resulted in the great improvement of life quality in cancer patients [65]. Research studies have exhibited immune-modulator effects of mango in different cell lines. The principle active constituents of mango consists of a mixture of terpenoids, polyphenols, steroids, fatty acids and microelements that imparts properties and provide antioxidant supplements [66].

4.17. Nervilia Fordii
*Nervilia fordii* is a drug used in China as a folklore remedy. Petroleum ether and ethyl acetate extracts of *Nervilia fordii* has been screened out for its anticancer properties using mice models. Both extracts have shown prominent anticancer effects when administered to S-180 mice and H-22 mice models; also prolong the life of cancer bearing mice. This study suggests, *Nervilia fordii*
can exploit as cancer-inhibiting agent and further research work is required to isolate active constituent/s present in drug [67].

4.18. Oroxylum Indicum

Oroxylum indicum (Sonapatha) is used in various polyherbal formulations in Indian system of medicine. Studies have proved anticancer potential of Oroxylum indicum using various models. A 95% ethanol extract exhibited cytotoxic activity against Hep2 cell lines at a concentration of 0.05% [68]. Flavonoid baicalein present in Oroxylum indicum has anti-tumour effect on human cancer cell lines and inhibited the 50% proliferation of HL-60 cell lines at a concentration of 25-30 microM [69]. Methanolic extract of O. indicum strongly inhibited the mutagenicity of Trp-P-1 in ames test [70]. Administration of nitrosated O. indicum fractions at a dose of 0.25-2 g/kg body weight has genotoxic and cell proliferative activity in the pyloric mucosa of rat stomach in vivo [71]. Extract of Oroxylum indicum showed the toxicity on tumor cell lines tested, with an IC50 value 19.6 μg/ml for CEM, 14.2 μg/ml for HL-60, 17.2 μg/ml for B-16 and 32.5 μg/ml for HCT-8 [72]. The methanolic and aqueous extracts of Oroxylum indicum have been demonstrated extensive cytotoxicity in selected tested cell lines, with the methanolic extract showing greater cytotoxic potential. Both extracts exhibited moderate levels of DNA protection against oxidative stress [73].

4.19. Picrorrhiza Kurroa

Picrorrhiza kurroa (Kutki) used as a hepatoprotective remedy in Indian system of medicine, inhibited liver cancer growth formed due to exposure of chemicals in animal studies. Kutkin is the active constituent of herb which is a combination of picroside and kutkoside. Kutkin is found to inhibit level of lipid peroxidases, hydroperoxidases, free radical producing agents and also facilitates the recovery of antioxidant SOD, which is needed to prevent the liver from oxidative damage [74].

4.20. Rubia Cordifolia

The hexapeptides and quinones found in Rubia cordifolia have shown a prominent antimutant activity by binding to eukaryotic 80S ribosomes. This binding resulted in inhibition of aminoacyl-tRNA binding and peptidyl-tRNA translocation, which is a necessary mechanism for protein synthesis [75,76,77]. Mollugin is a constituent that was isolated from chloroform extract of Rubia cordifolia roots. Mollugin has shown a significant activity against lymphoid leukemia in mice and also showed the inhibition of passive cutaneous anaphylaxis, protection of mast cells degranulation in rats [78]. A mitodepressive effect was observed on the rate of cell division in bone marrow of Swiss mice, which was attributed to the effect of inhibiting protein synthesis [79]. The cytotoxic action of Rubia cordifolia had been evaluated with DNA Topoisomerases I and II inhibition and cytotoxicity of constituents isolated from the roots was tested. Topoisomerases I and II inhibitory activities were measured by assessing the relaxation of supercoiled pBR 322 plasmid DNA. The tetrazolium-based colorimetric assay (MTT assay) was used for the cytotoxicity towards human colon carcinoma, human breast carcinoma and human liver carcinoma (HepG2) cell lines. Seven compounds were isolated possessing cytotoxic activity [80].

4.21. Salvia Miltiorrhiza

Tanshinone-I was isolated from traditional herb Salvia miltiorrhiza, was investigated on the expression of intercellular adhesion molecule. The study revealed a potential anticancer effect of tanshinone I on breast cancer cells, suggesting that tanshinone-I may serve as an effective drug for the treatment of breast cancer. [81]. Tanshinone II-A, isolated from Salvia miltiorrhiza, induced apoptosis which was linked to proteolytic cleavage of a major component in apoptotic cell death mechanism [82].

4.22. Scutellaria

Scutellaria is a genus of traditional herbal species with potential anti-cancer activity. Common biologically active flavonoids found in Scutellaria species are apigenin, baicalein, baicalin, chrysin, scutellarein, and wogonin. The flavonoids of Scutellaria species exhibited anti-tumor activity as well as positive interactions with different mechanism of actions. Among the different extracts tested, leaf extracts of Scutellaria angulosa, Scutellaria integrifolia, Scutellaria ocmulgee and Scutellaria scandens were found to possess a potent anticancer activity [83]. Yin et al., (2004) revealed the tumor inhibitory effect of Scutellaria barbata and explained its mechanism using human lung cancer cell line A549. Scutellaria barbata ethanol extract significantly reduced the growth of A549 cell, with an IC50 value of 0.21 mg/ml [84]. Tanshinone IIA, also isolated from herb might have potential anticancer activity on breast cancers, apoptosis, signal transduction, cell proliferation, transcriptional regulation, angiogenesis, invasive potential and metastatic potential of cancer cells [85]. Microarray and pathway analysis of tumor related genes identified the differentially expressed genes corresponding to tanshinone I and suggest that tanshinone I exhibits anticancer effects both in vitro and in vivo [86]. Other species of Scutellaria like S.baicalensis, Scutellaria litwinowii etc. have proved recently as a potent anticancer agent in various in vitro as well as in vivo models [87,88,89].

4.23. Silybum Marianum

Silymarinis a flavonoid compound isolated from the milk thistle plant Silybum marianum. Silymarin was studied against UV radiation induced skin cancer in mice. Silymarin treatment reduced the chances of tumor incidence to 60%, tumor multiplicity 78%, and tumor volume per mouse was also reduced to 90% and thus exhibited a prominent anticancer activity [90]. The probable mechanism of silymarin is its suppression of proliferation of tumor cells; this is accomplished through cell cycle arrest at the G1/S-phase, induction of cyclin-dependent kinase inhibitors, down-regulation of anti-apoptotic gene products, inhibition of cell-survival kinases and inhibition of inflammatory transcription factors. Silymarin was also found to down regulate gene
products associated in the proliferation of tumor cells, invasion, angiogenesis and metastasis [91]. Silibinin, a major constituent (flavanolignan) of the fruits of Silybum marianumalso beneficial in human breast cancer [92].

4.24. Smilax China

Kaempferol-7-O-beta-D-glucoside (KG), a flavonoid glycoside is the active constituent isolated from Smilax china L. rhizomes. KG has revealed a significant anticancer effect on cancer cells of which human cervix carcinoma cells were found more sensitive. It exerts its cytotoxic effect through arresting of cell cycle and induction of apoptosis in cells, suggesting that KG can be used as a therapeutic remedy for cervix carcinomas [93,94].

4.25. Strychnos Nuxvomica

Strychnos nuxvomica, belongs to the family Loganiaceae, is largely collected from forests of Indian subcontinent and Northern Australia. Strychnos nuxvomica has revealed cytotoxic activity against multiple myloma cell line- ROMI 8226. Root extract of Strychnos nuxvomica was screened using the same cell lines and exhibited anticancer activity in a dose and time dependent manner [95]. Major constituents present in Strychnos nuxvomicaare of alkaloidal nature and effective against HepG2 cells proliferation, among which brucine alkaloid proceed HepG2 cells death via apoptosis, through the participation of caspase-3 and cyclooxygenase-2 [96].

4.26. Taraxacum Officinale

Dandelions are common name of plants belong to genus Taraxacum. Taraxacum have a long history of use in several tribes and countries and also used to combat a wide variety of diseases including cancer. Leaves, flowers and root extracts of Taraxacum officinalewas investigated against tumor progression related processes such as invasion and proliferation. Among all the extracts, leaf extract of Taraxacum officinale decreased the growth of breast cancer cells [97]. The Taraxacum officinale decreased the cell viability and significantly increased the tumor necrosis factor (TNF)-α and interleukin (IL)-1α production [98].

4.27. Terminalia Chebula

Terminalia chebula is a source of hydrolysable tannis and its antimutagenic activity in Salmonella typhimuriumhas been documented [99]. Phenols like chebulinic acid, tannic acid, ellagic acid are the cancer growth inhibitors found in the fruits of Terminalia chebula [100]. Terminalia chebula fruits powder and its acetone extract of bark have been reported with promising antimutagenic and anticarcinogenic activity [101].

4.28. Vernononia Amygdalina

Vernonia amygdalina (VA), member of the Compositae family, is a small shrub that grows in the tropical Africa. The in vivo studies were conducted using sixty 5-6 week old female athymic nude mice. Mice were injected subcutaneously with 106 MCF-7 breast cancerous cells in the flank area and monitored for tumor growth. Compared to the negative control mice, VA completely reversed or eliminated the tumors of the animal in both treatment groups. Immuno histochemical data revealed that VA increased basal apoptotic but decreased angiogenic activities in both breast carcinomana cells [102].

4.29. Withania Somnifera (Withanolides)

Withaferin-A is a withanolide isolated from the roots of Withania somnifera. Withaferin-A has been shown a significant tumor reducing activity in carcinomas like carcinoma of nasopharynx, Sarcoma 180, Sarcoma Black and E 0771 mammary adenocarcinoma. Withania somnifera is highly appreciated in Ayurveda for cancer patients and also used as a folklore remedy for combating the cancer like conditions, also prolong the life [103,104,105].

The Withania somnifera root extract’s chemo preventive effect has been evaluated in a study on induced skin cancer in mice administering WS before and during exposure to the skin cancer causing agent 7, 12- dimethylbenz(a)anthracene. A significant decrease in incidence and average number of skin lesions was observe when compared to the control and standard groups [106]. An in vitro study showed withanolides from Withania somnifera reduced the growth of cancer cells in human breast, central nervous system, lung, and colon cancer cell lines comparable to doxorubicin, which was used as standard drug. Withaferin A was found more effective than standard drug doxorubicin [107]. Withania somnifera has also been evaluated for its antitumor effect in urethane induced lung adenomas in adult male albino mice. The histological appearance of the lungs of animals protected by Withania somnifera extract was found similar to those observed in the lungs of control animals. The treatment of drug extract also reversed the adverse effects of urethane on total leukocyte count, lymphocyte count, body weight, and mortality [108]. A significant increase in the life span and a decrease in the cancer cell number and tumour weight were noted in the tumour-induced mice after treatment with WS. These observations are suggestive of the protective effect of Withania somnifera in carcinogens [109].

4.30. Zingiber Officinale

Zingiber officinale ethanol extract was investigated to find out its antitumor effects in skin tumorigenesis model. Pre-application of Zingiber officinale ethanol extract onto the skin of mice resulted in significant inhibition of 12-O-tetradecanoylphorbol- 13-acetate (TPA)-caused induction of epidermal ODC, cyclo oxygenase, and lipoxygenase activities and ODC mRNA expression in adosedependent manner. Pre-application of Zingiber officinale ethanol extract to mouse skin also resulted in a significant inhibition of TPA caused epidermal edema and hyperplasia. In prolonged time studies, topical application of Zingiber officinale ethanol extract thirty minute prior to that of each TPA application to 7, 12-dimethylbenz(a)anthracene initiated mice caused a marked protection against skin tumor incidence its multiplicity [110].

Ginger’s natural bio-actives, specifically ginger extract and 6-gigerol, have also been investigated for their in vitro inhibition of two key aspects of colon cancer biology, cancer cell proliferation and angiogenic potential of endothelial cell tubule formation. These active ginger
constituents linked to a direct effect on cancer cells. Among other compounds, 6-gingerol was found more effective even at lower doses resulted in inhibition of endothelial cell tube formation [111]. The suggested mechanism of action of Ginger extract on colon cancer cells may be its suppression and arresting the G0/G1-phase, reducing DNA synthesis and inducing apoptosis [112].

</table>

Plants namely Azadirachta indica (Meliaceae), Boesenbergia pandurata (Zingiberaceae), Coscinium fenestratum (Menispermaceae) were extracted with 95% ethanol and tested for cytotoxic effects. The results showed that three plants, A. indica, B. pandurata, and C. fenestratum, exhibited high cytotoxic activity against the Hep2 cell lines at a minimum concentration of 0.05% in ethanol extract. In addition, C. fenestratum demonstrated
the most potent cytotoxic extract based on its lowest IC_{50} (5 mg/mL). All of these extracts resulted in a reduction of cell proliferation of Hep2 cells at four and eight hour’s incubation. When incubated for eight hour, Azadirachta indica and B. pandurata resulted in 95% inhibition of cell proliferation, while C. fenestratum provided 80% inhibitions respectively [68,73].

Calotropis, a glycoside present in Calotropis procera (Aak) has shown anti tumor activity against human epidermoid carcinoma cells of rhinopharynx in vivo studies [113]. Calotropis procera inhibited the growth of cells and mitotic activity in a dose-dependent manner in vitro [114]. Ellipticine, an indole alkaloid isolated from Ochrosia elliptica, is a potent topoisomerase inhibitor [115]. Curcumin, the active constituent of Curcuma domestica, has potent anticancer activity in animal models [116]. Homoharringtonine, an alkaloid from Cephalotaxus homoharringtonia, when combined with cytarabine, has shown activity in chronic myelogenous leukemia (CML) in a study 105 patients received continuous infusion of homoharringtonine 2.5 mg/kg/m2/day plus subcutaneous cytarabine 15 mg/kg/m2/day for five weeks. L-Canavanine isolated from Medicago sativa and Canavalia ensiformis, has shown significant antineoplastic activity in animal models bearing carcinoma and cancer cell lines [116,117].

5. Some Promising Plant-derived Anticancer ‘Leads’

Plants since the time immemorial have been regarded as a source of medicines and numerous types of bioactive substances have been isolated and characterized as therapeutic agents. A number of such molecules are under clinical studies. A synthetic flavone favopiridol, originally derived from the plant alkaloid rohitukine and isolated from Dyssoxylum binectariferum is currently under phase I and phase II clinical trials. This flavone has shown its broad activity against tumors, leukemia, lymphomas and solid tumors [122]. Olomucine is a natural product isolated from Raphanus sativus (Brassicaceae), has converted into a synthetic agent roscovitine. Roscovitine is in Phase II and Phase III clinical trials in Europe [123]. Isolation studies on the bark of Combretum caffrum (Combretaceae) resulted in the characterization of combretastatin [124]. Combretastatin A-4 has been found effective against lung and colon cancers, leukemia and it is presumed this is the most cytotoxic phytomolecule isolated so far [125,126]. Betulinic acid is a common pentacyclic triterpenoid found in the species of genus Betula has proved a significant growth inhibitory agent [127]. Betulinic acid was also isolated from Zizyphus species, like Zizyphusmauritiana, Zizyphusrugosa and Zizyphus oenoplia [128,129] and exhibited selective cytotoxic activity against human melanoma cell lines [130]. The efforts of National Cancer Institute to develop systemic and topical formulations for potential clinical trials are ongoing. Phytochemical studies on roots of Erythroxylum prvillei (Erythroxylaceae) has resulted in the isolation of Pervilleine-A [131]. In a study conducted on multidrug resistant oral epidermoid cancer cell lines, Pervilleine-A was found cytotoxic when administered with anticancer agent vinblastine and this compound is under preclinical development [132]. Silvesterol was isolated from the fruits of Meliaceae family plant Aglaila sylvestre exhibited cytotoxicity against breast and lung cancer cells [133]. Different studies are ongoing to determine the exact mechanism of action for silvesterol and other bioactive molecules [134]. Isolation studies on the seeds of Centarea schischkinii and Centarea montana has been resulted in the isolation of two novel alkaloids schischkinnin and montamine. Schischkinnin and montamine both exhibited anticancer activity against human cancer cells. The molecular skeleton of these novel alkaloids can be exploited for synthesizing compound to enhance cytotoxic activity [135].

5.1. Natural Products As Leads for Anticancer Drug Discovery

Epothilones are bacterial macrolides with potent microtubule-stabilizing and antiproliferative activity, which have served as successful lead structures for the discovery of several clinical candidates for cancer treatment. Seven epothilone-type agents have been advanced to clinical evaluation in humans so far and one of these has been approved by the FDA in 2007 for clinical use in breast cancer patients [136].

6. Conclusion

This review paper provides information on herbs and natural products with potential to decrease growth of cancer or be used as adjuvant with cancer treatments for patients who already have or have had cancer. It is documented that medicinal herbs have rich anticancer potential, and on the forefront whenever we talk about anticancer remedies, are significant source of synthetic and/or herbal origin. Natural products discovered from medicinal plants have played an important role in the treatment of cancer. They have exhibited anticancer activity in animal models of leukemia, skin cancer and sarcomas. Through generating awareness regarding usage of herbs and exploring natural product properties, healthcare professionals, can play significant clinical roles as knowledge resources for masses. From information from this review health care professionals can initiate discussion with colleagues to determine whether patient may benefit from from taking a specific herb or natural product. Selected plants have been explored for biological activity and further investigations into anticancer activity of the plants showing promising activity, must be undertaken. Vinca rosea alkaloids, Vinblastine and Vincristine, are one of the most potent anticancer drugs known. Taxol isolated from Taxus brevifolia has figured high in the therapeutic segment of cancer. Cancer being associated with high mortality rates if herbs can be used even in the palliative care or to reduce the side effects associated with cancer would be of great relief for the sufferer.
