Abstract In this paper we study and generalize some common fixed point theorems in compact and Hausdorff spaces for a pair of commuting mappings with new contraction conditions. The results presented in this paper include the generalization of some fixed point theorems of Fisher, Jungck, Mukherjee, Pachpatte and Sahu and Sharma.

Keywords: contraction mapping, fixed point, compact metric space

1. Introduction

Fixed point theory is a fascinating topic for research in modern analysis and topology. The study and research in fixed point theory began with the pioneering work of Banach [2], who in 1922 presented his remarkable contraction mapping theorem popularly known as Banach contraction mapping principle. It has widespread applications in both pure and applied mathematics. In 1961, Edelstein [8] for the first time introduced the concept of contractive mapping defined on compact metric spaces. According to Edelstein “if \( T \) is a continuous mapping of a compact metric space \( X \) into itself satisfying \( d(Tx,Ty)<d(x,y) \) for all \( x,y \in X, x \neq y \), then \( T \) has unique fixed point in \( X \)”. In 1976, Jungck [16] generalized contraction mapping theorem for a pair of commuting mappings. Later on several mathematicians have been generalized and improved The Banach contraction mapping theorem for fixed points in several different ways viz. Bondar [3], Browder [4], Chatterjee [5], Ciric [6] are a few to name. For more results in this direction, we refer to [12,13,19,20,22,23] and references therein. In this paper we want to establish some fixed point results in complete, compact and Hausdorff spaces for a pair of commuting mappings. The obtained results are generalizations of some fixed point theorems of Fisher [9], Jungck [16], Mukherjee [17], Pachpatte [18] and Sahu and Sharma [21].

The following fixed point theorems were proved in [9,16,17,18] and [21].

**Theorem 1.1.** [9] Let \( T \) be a mapping of the complete metric space \( X \) into itself satisfying the inequality

\[
(\alpha) (dx,dy)\leq \alpha_1 (dx,dy) + \alpha_2 (dx,dy)
\]

\( \forall x,y \in X, \ 0 \leq \alpha_1 < 1 \) and \( 0 \leq \alpha_2 \) then \( T \) has a fixed point in \( X \).

**Theorem 1.2.** [16] Let \( f \) be a continuous mapping of the complete metric space \( (X,d) \) into itself. Then \( f \) has a fixed point in \( X \) if and only if there exists \( \alpha \in (0,1) \) and a mapping \( g : X \to X \) which commutes with \( f \) and satisfies \( g(X) \subset f(X) \) and

\[
(\alpha) \leq ad(f(x),f(y))
\]

\( \forall x,y \in X \) then \( f \) and \( g \) have a common fixed point in \( X \).

**Theorem 1.3.** [17] Let \( f \) and \( g \) be mappings of a complete metric space \( X \) into itself with \( f \) continuous. Let \( f \) and \( g \) commute with each other and \( g(X) \subset f(X) \). Also, let \( g \) satisfy the following conditions:

\[
(\alpha) \leq \alpha_1 d(g(x),f(x)) + \alpha_2 d(g(y),f(y))
\]

\( \forall x,y \in X \) and \( \alpha_1 + \alpha_2 < 1 \) then \( f \) and \( g \) have a unique common fixed point in \( X \).

**Theorem 1.4.** [18] Let \( T \) be a mapping of the complete metric space \( X \) into itself satisfying the inequality

\[
(\alpha) (dx,dy)\leq \alpha_1 (dx,dy) + \alpha_2 (dx,dy)
\]

\( \forall x,y \in X \) and \( \alpha_1,\alpha_2 \geq 0 \) such that \( \alpha_1 + 2\alpha_2 < 1 \) then \( T \) has a unique fixed point.
Theorem 1.5. [21] Let $T$ be a mapping of the complete metric space $X$ into itself satisfy the conditions:

\[
(d(Tx, Ty))^2 \\
\leq a(d(x, TTx) + d(y, TTy) + d(x, Ty) + d(y, Tx)) \\
+ b(d(x, TTx) + d(y, TTy) + d(x, Ty) + d(y, Tx)) \\
+ c[d(y, Ty)]^2 + [d(x, Ty)]^2
\]

\forall x, y \in X$ and $a, b, c \geq 0$ such that $a + 2b + c < 1$, then $T$ has a unique fixed point in $X$.

2. Preliminaries

Definition 2.1. Let $(X, d)$ be a metric space. A mapping $T : X \to X$ is said to be a fixed point if for every sequence $(y_n)$ of $X$ if $\{Ty_n\}$ is convergent then $(y_n)$ has a convergent subsequence.

Definition 2.2. Let $T : X \to X$ be a continuous self-map of $X$ into itself. Then $T$ is said to be contractive if $d(Tx, Ty) < d(x, y)$ $\forall x, y \in X, x \neq y$.

Definition 2.3. If $X$ is a non empty set and $d : X \times X \to [0, \infty)$ is a mapping satisfying the conditions:

(i) $0 \leq d(x, y) \forall x, y \in X$ and $d(x, y) = 0$ if and only if $x = y$.

(ii) $d(x, y) = d(y, x) \forall x, y \in X$.

(iii) $d(x, y) \leq d(x, z) + d(z, y) \forall x, y, z \in X$.

Then $d$ is called a metric on $X$ and the pair $(X, d)$ is called a metric space.

Definition 2.4. A point $x \in X$ is said to be a fixed point of a self-map $T : X \to X$ if $T(x) = x$.

Definition 2.5. (i) A sequence $(x_n)$ in a metric space $(X, d)$ is said to converge to a point $x \in X$ if for every $\epsilon > 0$, there exists $N \in \mathbb{N}$ such that $d(x_n, x) < \epsilon$, $\forall n \in N$ denoted by $\lim_{n \to \infty} x_n = x$.

(ii) $(x_n)$ is called Cauchy sequence if for some $N \in \mathbb{N}$ there exists $\epsilon > 0$ such that for all $m, n \in N$, $m > n$ we have $\lim_{m, n \to \infty} d(x_m, x_n) = 0$.

(iii) A metric space $(X, d)$ is said to be complete if and only if every Cauchy sequence in $X$ converges to a point of $X$.

3. Main Results

In this section we prove our main results on the common fixed points of commuting self-mappings on complete, compact and Hausdorff spaces. We start with the following result.

Theorem 3.1. Let $(X, d)$ be a complete metric space and let $f, g : X \to X$ be commuting self maps of $X$ into itself with $f$ continuous such that $g(X) \subset f(X)$ and $g$ satisfy the conditions

\[
[d(g(x), g(y))]^2 \\
\leq a_1[d(f(x), g(x))]d(f(y), g(y)) \\
+ a_2[d(f(y), g(y))]^2 [1 + d(f(y), g(x))] \\
+ a_3[d(f(y), g(y))]d(g(x), g(y))(1 + d(f(y), g(x))) \\
+ a_4[d(f(x), g(y))]d(f(y), g(y))
\]

\forall x, y \in X$, where $a_1, a_2, a_3, a_4, a_5, a_6 \geq 0$ such that $a_1 + a_2 + a_3 + 2a_4 + a_5 < 1$.

Then $f$ and $g$ have a unique common fixed point in $X$.

Proof Let $x_0$ be an arbitrary point in $X$, then there exists $x_1 \in X$ such that $g(x_0) = f(x_1)$ we construct sequence $\{x_n\}$ in $X$ such that $g(x_n) = f(x_{n+1})$, since $g(X) \subset f(X)$ with $n = 0, 1, 2, 3, \ldots$ Now by using (3.1), we get

\[
[d(g(x_n), g(x_{n+1})]^2
\leq a_1[d(f(x_n), g(x_n))d(f(x_{n+1}), g(x_{n+1}))] \\
+ a_2[d(f(x_{n+1}), g(x_{n+1}))^2 [1 + d(f(x_{n+1}), g(x_n))] \\
+ a_3[d(f(x_{n+1}), g(x_{n+1}))d(g(x_n), g(x_{n+1})) \\
+ a_4[d(f(x_n), g(x_{n+1}))d(f(x_{n+1}), g(x_{n+1}))] \\
\]

\forall x, y \in X$, where $a_1, a_2, a_3, a_4, a_5, a_6 \geq 0$ such that $a_1 + a_2 + a_3 + 2a_4 + a_5 < 1$.

Then $f$ and $g$ have a unique common fixed point in $X$.
\[ +\alpha_2 \left[ d\left(f(x_n), f(x_{n+2})\right) d\left(f(x_{n+1}), f(x_{n+2})\right) \right] \]

\[
\alpha_5 \left[ \frac{\left(1 + d\left(f(x_{n+1}), f(x_n)\right)\right) d\left(f(x_{n+1}), f(x_{n+2})\right)}{1 + d\left(f(x_n), f(x_{n+1})\right)} \right]^2 \\
+ \alpha_6 \left[ \frac{d\left(f(x_{n+1}), f(x_{n+2})\right) d\left(f(x_{n+1}), f(x_{n+2})\right)}{1 + d\left(f(x_n), f(x_{n+1})\right)} \right]^2 
\]

or

\[
d\left(f(x_{n+1}), f(x_{n+2})\right) \leq \alpha_2 d\left(f(x_n), f(x_{n+1})\right) + \alpha_3 d\left(f(x_{n+1}), f(x_{n+2})\right) + \alpha_4 d\left(f(x_n), f(x_{n+2})\right) 
\]

or

\[
\left[ 1 - (\alpha_2 + \alpha_4 + \alpha_3) \right] d\left(f(x_{n+1}), f(x_{n+2})\right) 
\leq (\alpha_1 + \alpha_4) d\left(f(x_n), f(x_{n+1})\right) 
\Rightarrow d\left(f(x_{n+1}), f(x_{n+2})\right) \leq \frac{(\alpha_1 + \alpha_4)}{\left[ 1 - (\alpha_2 + \alpha_4 + \alpha_3) \right]} d\left(f(x_n), f(x_{n+1})\right) 
\]

where \( \eta = \frac{\alpha_1 + \alpha_4}{\left[ 1 - (\alpha_2 + \alpha_4 + \alpha_3) \right]} < 1 \). On continuous repetition of the above process, we get that \( \forall n \in \mathbb{N} \)

\[
d\left(f(x_{n+1}), f(x_{n+2})\right) \leq \eta^n d\left(f(x_1), f(x_0)\right) \quad (3.3) 
\]

on taking limit as \( n \to \infty \), we get

\[
\lim_{n \to \infty} d\left(f(x_{n+1}), f(x_{n+2})\right) = 0.
\]

Since \( X \) is complete, there exists \( z \in X \) such that

\[
\lim_{n \to \infty} g(x_n) = \lim_{n \to \infty} f(x_{n+1}) = z.
\]

Since \( f \) is continuous and \( f, g \) commute, we have

\[
fz = f\left( \lim_{n \to \infty} f_n \right) = \lim_{n \to \infty} f^2 x_n
\]

also

\[
fz = f\left( \lim_{n \to \infty} g_n \right) = \lim_{n \to \infty} fg_n = \lim_{n \to \infty} gf_n.
\]

Now by (3.1) we have

\[
\left[ d\left(g(f(x_n)), g(g(z))\right)\right]^2 
\leq \alpha_1 \left[ d\left(f(x_n), g(f(x_n))\right) d\left(f(g(z)), g(g(z))\right)\right] 
\]

\[
+ \alpha_2 \left[ d\left(f(g(z)), g(g(z))\right)\right]^2 
\]

\[
\left[ 1 + d\left(f(g(z)), g(f(x_n))\right)\right] 
\]

On taking limit as \( n \to \infty \) and use continuity, we obtain

\[
\left[ d\left(f(z), g(g(z))\right)\right]^2 
\leq \alpha_1 \left[ d\left(f(z), f(z)\right) d\left(f(g(z)), g(g(z))\right)\right] 
\]
We now prove that \( g(z) \) is a common fixed point of \( f \) and \( g \). By (3.1) we have

\[
\begin{align*}
&+\alpha_2 \left[ d(f(g(z)), g(g(z)))^2 \left( 1 + d(f(g(z)), f(z)) \right) \right] \\
&+\alpha_3 \left[ d(f(g(z)), g(g(z)))^2 \left( 1 + d(f(g(z)), f(z)) \right) \right] \\
&+\alpha_4 \left[ d((f(z), g(z))d(f(g(z), g(g(z)))) \right] \\
&+\alpha_5 \frac{\left( 1 + d(f(z), f(z)) \right) d(f(g(z)), g(g(z)))^2}{\left( 1 + d(f(z), f(z)) \right)} \\
&+\alpha_6 \frac{\left( 1 + d(f(z), f(z)) \right) d(f(g(z)), g(g(z)))^2}{\left( 1 + d(f(z), f(z)) \right)} \\
&\Rightarrow [1 - (\alpha_2 + \alpha_3 + \alpha_4 + \alpha_5 + \alpha_6)]d(f(z), g(g(z))) \leq 0.
\end{align*}
\]

This implies that \( f(z) = g(g(z)) \).

We now prove that \( g(z) \) is a common fixed point of \( f \) and \( g \). By (3.1) we have

\[
\begin{align*}
&\left[ d(g(g(z)), g(z)) \right]^2 \\
&\leq \alpha_1 \left[ d(f(g(z)), g(z))d(f(z), g(g(z))) \right] \\
&+\alpha_2 \left[ d(f(z), g(z))^2 \left( 1 + d(f(z), g(g(z))) \right) \right] \\
&+\alpha_3 \left[ d(f(z), g(z))d(g(g(z)), g(z)) \right] \\
&\Rightarrow [1 - (\alpha_2 + \alpha_3 + \alpha_4 + \alpha_5 + \alpha_6)]d(f(z), g(g(z))) \leq 0.
\end{align*}
\]

Hence, we have \( f(g(z)) = g(f(z)) = g(g(z)) = f(z) = g(z) \).

Uniqueness: To see that \( f \) and \( g \) have only one common fixed point. Suppose \( z_1 = f(z_1) = g(z_1) \) and \( z_1 = f(z_1) = g(z_1) \). By (3.1) we get

\[
\begin{align*}
&\left[ d(z_1, z_2) \right]^2 = \left[ d(g(z_1), g(z_2)) \right]^2 \\
&\leq \alpha_1 \left[ d(f(z_1), g(z_1))d(f(z_2), g(z_2)) \right] \\
&+\alpha_2 \left[ d(f(z_2), g(z_2))^2 \left( 1 + d(f(z_2), g(z_1)) \right) \right] \\
&+\alpha_3 \left[ d(f(z_2), g(z_2))d(g(z_1), g(z_2)) \right] \\
&+\alpha_4 \left[ d(f(z_1), g(z_1))d(f(z_2), g(z_2)) \right] \\
&\Rightarrow [1 - (\alpha_2 + \alpha_3 + \alpha_4 + \alpha_5 + \alpha_6)]d(f(z_1), g(z_2)) \leq 0
\end{align*}
\]
and thus we have
\[ d(x_1, x_2) \leq a_1 d(x_2, x_1) + a_2 d(x_1, x_2) \]
which shows the uniqueness of fixed point of \( f \) into itself such that \( \alpha \) is a metric on \( X \) is a complete metric space and \( \alpha \) commute with each other such that \( g(X) \subset f(X) \) and \( \alpha \) satisfy the following condition:
\[
\begin{align*}
\left[ d(g(x_1), g(x_2)) \right]^2 &\leq a_1 \left[ d(x_1, x_2) \right]^2 + a_2 \left[ d(y_1, y_2) \right]^2 + a_3 \left[ d(y_1, y_2) \right] \left[ d(y_1, y_2) \right] + a_4 \left[ d(y_1, y_2) \right] \\
&+ a_5 \left[ \frac{d(x_1, x_2)}{1 + d(x_1, x_2)} \right]^2 + a_6 \left[ \frac{d(y_1, y_2)}{1 + d(y_1, y_2)} \right]^2
\end{align*}
\]
\[ \forall x, y \in X, \ x \neq y \text{ and } a_1 \geq 0 \text{ with } a_1 + 2a_2 + a_3 + 2a_4 + a_5 = 1 \]
then \( g \) has a unique fixed point in \( X \).

**Remark:** If we put \( a_6 = 0 \) then we get theorem (1.3) in [17].

**Remark:** If we put \( a_2 = a_3 = a_4 = a_5 = a_6 = 0 \), then we get theorem (1.1) in [16].
Suppose \( f \) is continuous, there exists \( \alpha \) such that
\[
\left| f(x_n) - f(x_{n+1}) \right| \leq \alpha \left| x_n - x_{n+1} \right|
\]
and so
\[
\lim_{n \to \infty} d_n = \lim_{n \to \infty} \left\{ d(f(x_n), f(x_{n+1})) \right\} = d.
\]

Since \( X \) is compact, using sequential compactness of \( X \), there exists a subsequence \( \{ x_{n_k} \} \) of \( \{ x_n \} \) such that for any \( u \in X \) and \( k \to \infty \), we get
\[
\lim_{k \to \infty} x_{n_k} = u.
\]

Now, we use the continuity of \( g \) and \( d \) to obtain
\[
d_{n_k} = d(x_{n_k}, x_{n_k+1}) = d(x_{n_k}, gx_{n_k}) \to d(u, gu) \text{ as } k \to \infty.
\]

Since \( d_{n_k} \to d \), we have \( d = d(u, gu) \). Similarly,
\[
d_{n_{k+1}} = d(x_{n_{k+1}}, x_{n_{k+2}}) = d(gx_{n_k}, gx_{n_k}) \to d(gu, gu) = d \text{ as } k \to \infty. \tag{3.6}
\]

Since the sequence \( \{ d_{n_{k+1}} \} \) is a subsequence of the sequence \( \{ d_n \} \), we get
\[
d = d(u, gu) = d(gu, gu).
\]

Next we claim \( d = 0 \). Suppose \( d \neq 0 \), then \( u \neq gu \). By (3.6) we obtain
\[
d = \lim_{k \to \infty} d_{n_{k+1}} = \lim_{k \to \infty} d \left( g(x_{n_k}), g(gx_{n_k}) \right) = d(g(u), g(g(u))) < d(u, g(u)) = d
\]
which is contradiction, hence \( d = 0 \). Hence,
\[
\lim_{n \to \infty} d(f(x_n), f(x_{n+1})) = 0. \tag{3.7}
\]

Since \( x_{n_k} = f_{n+1} \) for each \( n = 0, 1, 2, \ldots \). From (3.7), we get
\[
\inf \{ d(f(x), g(x)) : x \in X \} = 0. \tag{3.8}
\]

Since the mapping \( d : X \to \mathbb{R}^+ \) defined by \( d(f(x), g(x)) \) is continuous, there exists \( z \in X \) such that
\[
d(f(z), g(z)) = \inf \{ d(f(x), g(x)) : x \in X \}.
\]

By (3.8) \( d(f(z), g(z)) = 0 \) and so \( f(z) = g(z) = v \). Now, since \( f \) and \( g \) commute, we have
\[
f(v) = f(g(z)) = g(f(z)) = g(v).
\]

Thus
\[
f(v) = g(v) = v \tag{3.9}
\]
and so \( v \) is a common fixed point of \( f \) and \( g \).

**Uniqueness:** Next we claim that \( v \) is the unique common fixed point of \( f \) and \( g \). Suppose on the contrary that there exists another point \( w \in X \) such that \( f(w) = g(w) = w \) with \( f(w) \neq f(v) \). Using condition (3.4) we get
\[ [d(v,w)]^2 = [d(g(v),g(w))]^2 \]
\[ \leq \alpha_1 [d(f(v),g(v))] [d(f(w),g(w))] + \alpha_2 [d(f(w),g(w))^2 (1+d(f(w),g(v))] + \alpha_3 [d(f(w),g(v))] + \alpha_4 [d(f(v),g(w))] \]
\[ \leq \alpha_1 [d(v,v)] [d(w,w)] + \alpha_2 [d(w,w)^2 (1+d(w,v))] + \alpha_3 [d(w,v)] + \alpha_4 [d(v,w) \leq 0 \Rightarrow [d(v,w)]^2 \leq 0 \]

which implies that \( d(v,w) = 0 \) or \( v = w \) and this gives the uniqueness of the fixed point.

**Corollary 3.4.** Let \((X,d)\) be a compact metric space and let \( f, g : X \rightarrow X \) be self mappings of \( X \) satisfying the condition

\[ [d(g(x),g(y))]^2 \leq \alpha_1 [d(f(x),g(x))] [d(f(y),g(y))] + \alpha_2 [d(f(y),g(y))^2 (1+d(f(y),g(x))] + \alpha_3 [d(f(y),g(y))] + \alpha_4 [d(f(x),g(y))] \]
\[ \leq \alpha_1 [d(x,x)] [d(y,y)] + \alpha_2 [d(y,y)^2 (1+d(y,y))] + \alpha_3 [d(y,y)] + \alpha_4 [d(x,y) \leq 0 \Rightarrow [d(x,y)]^2 \leq 0 \]

**Proof** Putting \( \alpha_1 = \alpha_2 = a, \ \alpha_3 = \alpha_4 = b, \) and \( \alpha_5 = c \) in Theorem (3.3) we get the required result.

**Corollary 3.5.** Let \((X,d)\) be a complete compact metric space and \( g \) be a self mapping \( g : X \rightarrow X \) satisfying

\[ [d(g(x),g(y))]^2 \leq \alpha_1 [d(x,x)] [d(y,y)] + \alpha_2 [d(y,y)^2 (1+d(y,y))] + \alpha_3 [d(y,y)] + \alpha_4 [d(x,y) \leq 0 \Rightarrow [d(x,y)]^2 \leq 0 \]

for all \( x, y \in X \) and \( \alpha_1, \alpha_2, \alpha_3, \alpha_4 \geq 0 \) such that \( \alpha_1 + \alpha_2 + \alpha_3 + 2\alpha_4 = 1 \), then \( g \) has a unique fixed point in \( X \).

**Proof** Putting \( \alpha_5 = 0 \) and \( f = I \) (Identity mapping) in Theorem (3.8), we get the required result.

**Corollary 3.6.** Let \((X,d)\) be a compact metric space and \( g : X \rightarrow X \) be a self map of \( X \) into itself satisfying the inequality

\[ [d(g(x),g(y))]^2 \leq \alpha_1 [d(x,x)] [d(y,y)] + \alpha_2 [d(y,y)^2 (1+d(y,y))] \]

for all \( x, y \in X \), such that \( \alpha_1 + 2\alpha_2 = 1 \), then \( g \) has a unique fixed point in \( X \).

**Proof** Putting \( \alpha_3 = \alpha_4 = \alpha_5 = \alpha_6 = 0 \) in Theorem (3.8) we get the required result

**Remark:** Corollary (3.4) is the result of Sahu and Sharma in [21]

**Remark:** Corollary (3.5) is the result of Pachpatte [18]

Remark: Corollary (3.6) is the result of Fisher [9]

Now we give an example to support the validity of the above theorem (3.3).

**Example:** Let \( X = \{1,5,9\} \) be any non-empty set and let \( d \) be the metric with ordinary distance. Let the functions \( f \) and \( g \) on \( X \) be defined by

\[ f(1) = 5, \ f(5) = 1, \ f(9) = 9 \]
\[ g(1) = 5 = g(5) = 9 \]

Then it is clear that \( g(X) \subset f(X) \) with \( f \) and \( g \) commute, continuous and \((X,d)\) is a compact metric space. Now it is easy to show that the above example satisfy all the conditions of Theorem (3.3) with 9 as the only common fixed point in \( X \).

**Theorem 3.7.** Let \( f \) and \( g \) be two continuous mappings of a hausdorff space \( X \) into itself and let \( f, g \) commute with each other such that \( g(X) \subset f(X) \). Let \( F : X \times X \rightarrow R^+ \) be a continuous function such that for each pair of \( x, y \in X \) with \( f(x) \neq f(y) \)

\[ [d(g(x),g(y))]^2 \leq \alpha_1 [d(x,x)] [d(y,y)] + \alpha_2 [d(y,y)^2 (1+d(y,y))] + \alpha_3 [d(y,y)] + \alpha_4 [d(x,y) \leq 0 \Rightarrow [d(x,y)]^2 \leq 0 \]
such that

has a convergent sequence. Then (3.11) gives us

\[
\alpha_1 \geq 0 \quad \text{such that } \alpha_1 + \alpha_2 + \alpha_3 + 2\alpha_4 + \alpha_5 < 1. \quad \text{If for some } x_0 \in X, \text{ the sequence } \{x_n\} \text{ in } X \text{ has a convergent subsequence. Then } f, g \text{ have a common fixed point.}
\]

**Proof** Since \( g(X) \subset f(X) \). So, for \( x_0 \in X \), we choose \( x_1 \in X \) such that \( g(x_0) = f(x_1) \) with the sequence \( \{x_n\} \) defined by

\[
g x_0 = f x_1, g x_1 = f x_2, \ldots, g x_{n-1} = f x_n, \quad g x_n = f x_{n+1}, n = 0, 1, 2, 3, \ldots
\]

Now by (3.10) we have

\[
\left[ F(f(x), g(y)) \right]^2 \\
\leq \alpha_1 \left[ F(f(x), g(y)) F(f(y), g(y)) \right] \\
+ \alpha_2 \left[ \left( 1 + F(f(y), g(x)) \right) \right]^2 \\
+ \alpha_3 \left[ \left( f(y), g(y) \right) \right] \\
+ \alpha_4 \left[ F(f(y), g(y)) \right] \\
+ \alpha_5 \left[ \left( 1 + F(f(y), g(y)) \right) \right]^2 \\
+ \alpha_6 \left[ \left( 1 + F(f(y), g(y)) \right) \right]^2
\]

or

\[
F(x_{n+1}), f(x_{n+2}) \leq \left( \alpha_1 + \alpha_2 \right) F(x_0), f(x_1)
\]

Let \( y_n = f(x_n) \forall n \in N. \) Then (3.11) gives us

\[
F(y_1, y_2) = F(f(x_1), f(x_2)) \\
\leq \left( \alpha_1 + \alpha_4 \right) F(x_0), f(x_1)
\]

Similarly,

\[
F(y_2, y_3) = F(f(x_2), f(x_3)) \\
\leq \left( \alpha_1 + \alpha_4 \right) F(x_0), f(x_1)
\]

Since \( \alpha_1 + \alpha_2 + \alpha_3 + 2\alpha_4 + \alpha_5 < 1. \)

Repeating the above process, we get

\[
F(y_{n+1}) \geq F(y_{n+2}) \geq \ldots \geq F(y_{n}, y_{n+1}) \geq \ldots
\]

This shows that the sequence \( F(y_{n}, y_{n+1}) \) is bounded which converges along with all its subsequences to some positive real number \( z \). If \( \{y_n\} \) has a convergent subsequence of \( \{y_{n_k}\} \) which converges to the real number \( z \), then

\[
F(z, g(z)) = F \left[ \lim_{k \to \infty} y_{n_k}, g \left( \lim_{k \to \infty} y_{n_k} \right) \right]
\]

\[
= F \left[ \lim_{k \to \infty} y_{n_k}, g \left( \lim_{k \to \infty} y_{n_{k+1}} \right) \right]
\]

\[
= F \left[ \lim_{k \to \infty} y_{n_{k+1}}, y_{n_{k+2}} \right]
\]

\[
= F \left[ \lim_{k \to \infty} y_{n_{k+1}}, \lim_{k \to \infty} y_{n_{k+2}} \right]
\]

\[
= F \left[ g \lim_{k \to \infty} y_{n_k}, g \lim_{k \to \infty} y_{n_k} \right]
\]

\[
= F \left( g(z), g(z) \right).
\]
Next we show that \( z \) is a fixed point of \( f \) and \( g \). First we show that \( z \) is a fixed point of \( g \). Suppose, \( g(z) \neq z \), then by (3.5) we have
\[
\left[ F(z, g(z)) \right]^2 = \left[ F(g(z), g(g(z))) \right]^2
\]
\[
\leq a_1 \left[ F(f(z), g(z)) F(f(g(z)), g(g(z))) \right]
+ a_2 \left[ \frac{F(f(g(z)), g(g(z)))^2 (1 + F(f(g(z)), g(g(z))) \right]
+ a_3 \left[ F(f(g(z)), g(g(z))) \frac{1 + F(f(g(z)), g(g(z))) \right]
+ a_4 \left[ F(f(g(z)), g(g(z))) \right]
+ a_5 \left[ \frac{1 + F(f(g(z)), g(g(z))) \right]
+ a_6 \left[ \frac{F(g(z), g(g(z))) \right]
\leq a_1 \left[ F(g(z), g(g(z))) \right]
+ a_2 \left[ F(g(z), g(g(z))) \right]
+ a_3 \left[ F(g(z), g(g(z))) \right]
+ a_4 \left[ F(g(z), g(g(z))) \right]
+ a_5 \left[ F(g(z), g(g(z))) \right]
+ a_6 \left[ F(g(z), g(g(z))) \right]
\]

or
\[
F(z, g(z)) \leq a_2 F(z, g(z)) + a_3 F(z, g(z)) + a_4 F(z, g(z))
+ a_5 F(z, g(z)) + a_6 F(z, g(z))
\Rightarrow \left[ 1 - (a_2 + a_3 + a_4 + a_5) \right] F(z, g(z)) \leq 0
\]
which is contradiction because \( a_1 + a_2 + a_3 + 2a_4 + a_5 < 1 \).

Hence, \( F(z, g(z)) = 0 \Rightarrow z = g(z) \). Thus, \( z \in X \) is a fixed point of \( g \). Since \( f \) and \( g \) commute and are continuous, we have
\[
f \left( g \left( y_{n_k} \right) \right) \rightarrow f(z)
\]
and \( g \left( f \left( y_{n_k} \right) \right) \rightarrow g(z) \) as \( k \rightarrow \infty \)
\[
f \left( y_{n_k} \right) \rightarrow g \left( f \left( y_{n_k} \right) \right) \rightarrow g(z) \] as \( n_k \rightarrow \infty \).

By the uniqueness of limit we have
\[
f(z) = g(z) = z.
\]

**Uniqueness:** Now we claim that \( z \) is the unique common fixed point of \( f \) and \( g \). Suppose for contradiction that \( w \) is another fixed point of \( f \) and \( g \) such that \( f(w) = g(w) = w \) then by (3.10) we obtain
\[
\left[ F(z, w) \right]^2 = \left[ F(g(z), g(w)) \right]^2
\]
\[
\leq a_1 \left[ F(f(z), g(w)) F(f(g(w)), g(g(w))) \right]
+ a_2 \left[ \frac{F(f(g(w)), g(g(w)))^2 (1 + F(f(g(w)), g(g(w))) \right]
+ a_3 \left[ F(f(g(w)), g(g(w))) \frac{1 + F(f(g(w)), g(g(w))) \right]
+ a_4 \left[ F(f(g(w)), g(g(w))) \right]
+ a_5 \left[ \frac{1 + F(f(g(w)), g(g(w))) \right]
+ a_6 \left[ \frac{F(g(w), g(g(w))) \right]
\leq a_1 \left[ F(g(w), g(g(w))) \right]
+ a_2 \left[ F(g(w), g(g(w))) \right]
+ a_3 \left[ F(g(w), g(g(w))) \right]
+ a_4 \left[ F(g(w), g(g(w))) \right]
+ a_5 \left[ F(g(w), g(g(w))) \right]
+ a_6 \left[ F(g(w), g(g(w))) \right]
\]

This implies that \( \left[ F(z, w) \right]^2 \leq 0 \) which is contradiction because
\[
a_1 + a_2 + a_3 + 2a_4 + a_5 < 1.
\]

Hence, \( \left[ F(z, w) \right]^2 = 0 \Rightarrow z = w \). Hence \( z \) is the unique common fixed point of \( f \) and \( g \).

Finally, we provide example to check the validity of Theorem (3.7).

**Corollary 3.8.** Let \( g : X \rightarrow X \) be a continuous mappings of a haudorff space \( X \) into itself and let \( F : X \times X \rightarrow R^+ \).
be a continuous function such that for each pair of \( x, y \in X \) with \( \mathcal{F}(x) \neq \mathcal{F}(y) \)

\[
\left[ \mathcal{F}(g(x), g(y)) \right]^2 \leq \alpha_1 \left[ \left( \mathcal{F}(f(x), g(x)) \right) \mathcal{F}(f(y), g(y)) \right] + \alpha_2 \left[ \left( \mathcal{F}(g(x), y) \right) \mathcal{F}(g(y), x) \right] \\
+ \alpha_3 \left[ \left( \mathcal{F}(f(y), g(y)) \right) \mathcal{F}(f(x), g(x)) \right] + \alpha_4 \left[ \left( \mathcal{F}(g(y), x) \right) \mathcal{F}(g(x), y) \right] \\
+ \alpha_5 \left[ \left( \mathcal{F}(f(x), g(x)) \right) \mathcal{F}(f(y), g(y)) \right] + \alpha_6 \left[ \left( \mathcal{F}(g(x), y) \right) \mathcal{F}(g(y), x) \right]
\]

and \( \alpha_j \geq 0 \) such that

\[
\alpha_1 + \alpha_2 + \alpha_3 + 2\alpha_4 + \alpha_5 \leq 1
\]

If for some \( x_0 \in X \), the sequence \( \{x_n\} \) in \( X \) has a convergent subsequence. Then \( f \) has a unique fixed point in \( X \).

**Proof** Put \( f = I_X \) (Identity mapping) in Theorem (3.7) we get the required result.

**Corollary 3.9.** Let \( f \) and \( g \) be two continuous mappings of a Hausdorff space \( X \) into itself and let \( f \) and \( g \) commute with each other such that \( g(X) \subset f(X) \). Let \( \mathcal{F} : X \times X \to \mathbb{R}^+ \) be a continuous function such that for each pair of \( x, y \in X \) with \( \mathcal{F}(x) \neq \mathcal{F}(y) \)

\[
\left[ \mathcal{F}(g(x), g(y)) \right]^2 \leq \alpha_1 \left[ \left( \mathcal{F}(f(x), g(x)) \right) \mathcal{F}(f(y), g(y)) \right] + \alpha_2 \left[ \left( \mathcal{F}(f(y), g(y)) \right) \mathcal{F}(f(x), g(x)) \right] \\
+ \alpha_3 \left[ \left( \mathcal{F}(g(x), y) \right) \mathcal{F}(g(y), x) \right] + \alpha_4 \left[ \left( \mathcal{F}(g(y), x) \right) \mathcal{F}(g(x), y) \right] \\
+ \alpha_5 \left[ \left( \mathcal{F}(f(x), g(x)) \right) \mathcal{F}(f(y), g(y)) \right] + \alpha_6 \left[ \left( \mathcal{F}(g(x), y) \right) \mathcal{F}(g(y), x) \right]
\]

and \( \alpha_1, \alpha_2 \geq 0 \) such that \( \alpha_1 + \alpha_2 < 1 \). If for some \( x_0 \in X \), the sequence \( \{x_n\} \) in \( X \) has a convergent subsequence. Then \( f \) has a common fixed point.

**Proof** Put \( \alpha_3 = \alpha_4 = \alpha_5 = \alpha_6 = 0 \) in Theorem (3.7) we get Corollary (3.9).

**Remark:** Corollary (3.8) is the result of [17]

**Remark:** Corollary (3.9) is the result of [5]

**Example:** Let \( X = \{3, 4, 5\} \). We define \( \mathcal{F} : X \times X \to [0, \infty) \) and \( f, g : X \to X \) by

\[
\mathcal{F}(x, y) - \mathcal{F}(x, y) = \mathcal{F}(f(y), x) \forall x, y \in X
\]

with \( \mathcal{F}(3, 4) = \mathcal{F}(4, 5) = \mathcal{F}(4, 5) = 2 \)

and \( \mathcal{F}(3) = \mathcal{F}(4) = \mathcal{F}(5) = 5 \).

Now, it is clear that the conditions of Theorem (3.7) are satisfied and that 5 is the common fixed point of \( f \) and \( g \).
