Abstract Wild edible mushrooms are vegetables proteins sources used for centuries with appreciate nutritional and medical properties This study aimed to characterize common popular mushroomms in Southwest region (Burkina Faso) and determine their nutritional value. A field survey combined with interviews were carried out with 225 people for the collection of relative data. Standards methods was used for proximate compound analysis, minerals content, ascorbic acid and beta caroten determination. The results put in evidence *Agaricus campestris*, *volvariella volvacea*, *cantharellus stramineus* as popular mushrooms spesies in this area. Harvesting is more abundant between jully and september and dried and smoked are the main preservation process. Proximate composition (g/100g) showed appreciate values of moister content (7.54 ± 0.09 to 8.48 ± 0.06), acidity (5.94 ± 0.00 o 49.05 ± 0.33), crude proteins ($23.03 \pm 0.38\%$ to 36.77 ± 0.3), lipids (2.25 ± 0.04 to 2.69 ± 0.4) carbohydrates (24.797 ± 0.59 to 28.78 ± 0.7), fibers (26.39 ± 0.58 to 46.70 ± 0.55), ash (11.22 ± 0.47 to 25.03 ± 0.27), and energy (213.20 ± 2.75 to 286.83 ± 3.50 kcal/100g). Beta-carotene content was ranged from 0 to 4.260 ± 0.04 mg/100g (*Volvariella volvacea*), while ascorbic acid (Vitamin C) content varied from 0.103 ± 0.02 mg/100g (*Volvariella volvacea*) to 0.256 ± 0.00 mg/100g (*Agaricus campestris*). Minerals content (mg/100g) showed a content of K (1476 to 2830), Mg (46.93 to 194.03), Na (20.5 to 49.2) Ca (19.28 to 195.94), Zn (3.97 to 4.86), Fe (2.92 to 14.29). Mn (1.78 to 9.95) and Cu (1.14 to 3.89). Wild edible mushrooms have appreciated nutritional value, but only available during raining season. As they are treathened by both climate change and human activities. Initiatives to safeguard them may inculde either creating biobank or through domestication and demonstrating their detailed nutritional values and safety.

Keywords: Wild edible mushrooms, Burkina Faso, Proximate, Minerals, Vitamins

1. Introduction

Worldwide ethnomycological knowledge reveals that wild edible mushrooms have been used by humans since ancestral times either as food, medicine, or for ceremonial purpose [1]. The world's mycological flora is estimated to be over 1.5 million species, about six times more than vascular plants' flora [2]. Curently, both climate change and human activities are significantly reducing both

mushrooms diversity and picking quantity [1]. Mushrooms play key role in both human health, economy, and environment. Conserving environmental issues, mushrooms promote forest sustainability, biodiversity conservation, conservation of biocultural heritages, and mitigation of greenhouse gas emissions through the maintenance of forest masses. [3]. On the economic side, mushrooms contribute significantly to economic development, job creation, and youth and women empowerment. The worldwide mushroom production has amounted 5 million tons [4]. Mushroom cultivation has

increased over the last decade in many parts of the world. It is carried out in more than 100 countries with an annual growth rate of 6-7% [5]. China is the world's leading country in the cultivation of both edible and medicinal mushrooms, with over 80% of the world production. In China, it created over 25 million job opportunities [6].

In African countries, mushrooms cultivation began early but is in progress. In economic terms, harvesting and marketing them generate substantial income for local communities, particularly women, who sell them fresh or dried on the markets [7,8,9,10]. In Tanzania for example, the wild mushroom collection is a socio-economic activity among the Hehe and Benna communities. It is estimated that the collectors earn approximately US \$500 to 1000 for 750 - 1500kg of mushrooms per season [11]. Mushrooms also contribute for human nutrition, health and hunger mitigation. Wild edible wild mushrooms are among the non-timber forest products (NTFPs) that are frequently and intensively consumed in low-income households, contributing to the diversification of their daily diet and the dietary balance, especially during the lean season [12,13,14]. Mushrooms are a rich source of several nutrients, including protein, fibre and micronutrients such as vitamins (C, D and B group vitamins) (Groves, 1981). They also contain essential minerals (potassium, phosphorus, selenium), playing a crucial role in combating nutritional deficiencies. Their content of bioactive compounds, such as antioxidants [15,16] and antibacterial and antifungal agents [17], also enhances health benefits. In Burkina Faso, previous works identified thirty-one (31) species of nineteen (19) genera of edible mushrooms [18]. However, the Southwest region has not been sufficiently investigated [19,20] despite the fact that it's the main region where people mostly gather wild edible mushrooms during the rainy season. Climate change, farming and gold mining, agricultural exploitation and gold mining are the greatest threats to the diversity and disappearance of mushrooms in this region. There is then a need for endogenous edible mushrooms especes domestication and cultivation. This study aims to document traditional mushrooms utilizations, ecology and nutrition in southwest part of Burkina Faso for domestication purpose.

2. Material and Methods

2.1. Survey on Wild Edible Mushrooms Utilization in Southwestern Burkina Faso

A survey questionnaire was elaborated using SphinxPlus.V5.TuiTe software. A total of 225 houses were surveyed in selected communes in Poni province based on their mushroom's picking importance: Gaoua (50), Périgban (25), Kampti (25), Loropéni (25), Bousséra (50), and Gbomblora (50). The questions included a listing of available and consumed wild edible mushrooms in the area, their harvesting period. Wild edible mushrooms' uses and preservation process were also recorded. Another questionnaire was used to describe the ecology and morphological characteristics of each

mushroom species. Mushroom identification guide has been used for basic identification of the inventoried species.

Figure 1.

2.2. pH and Acidity Determination

For pH measurement, 10 g of each mushrooms sample were dissolved in 50 ml of sterile demineralized water. The pH was then directly measured with a numeric pH-meter (WTW multi line P4). For acidity determination, 10 g of each sample were made into slurry using 50 ml distilled water in a flask. Then 10 mL of the slurry was titrated against 0.1 N KOH using phenolphthalein as indicator; the total titratable acidity was then calculated as a percentage.

2.3. Proximate Composition

Moisture content was determined using oven drying method according to ISO-712 [21] while pH and acidity was determined based on ISO-750 [22] method. Proximate composition of the samples was determined using standards methods described by the Association of Official Analytical Chemists [23]: Dry matter by drying mushrooms samples at 105°C overnight, ash by incineration at 550°C for 12h. Crude protein content (N×6.25) was determined by the Kjeldahl method [24], and crude fat content by Soxhlet extraction using n-hexane as solvent. Total carbohydrate content was determined by the phenol sulphuric acid method according to Tollier and Robin [25] and the values were expressed in g/100 g of mushrooms. Crude fibres content was determined according to AOAC's standard methods. The energy value was calculated using the method described by Merrill and Watt [26].

2.4. Mineral Analysis

For minerals, calcium (Ca), magnesium (Mg), iron (Fe), zinc (Zn), sodium (Na), potassium (K), phosphorus (P), copper (Cu) analysis, mushrooms samples were firstly wet (0.5 g) and digested. The digested mushrooms samples were then analyzed in Atomic Absorption spectrophotometer and each selected minerals were quantified according to the Association of Official Analytical Chemists Approved method [27].

2.5. Vitamins Determination

Ascorbic acid content was determined by High Performance Liquid Chromatography (HPLC) using Velde et al., [28] methods. Beta-carotene content of mushrooms was determined by HPLC using the AOAC method [29]. β -Carotene content was determined from mushrooms dried ethanol extract according to Kumari et al. [30]. Then, 100 mg of extract was mixed with 10 mL of acetonitril for 3 min and filtered. The β -carotene content was determined in mg/100g.

XLSTAT software version 2016 was used for analysis of variance (ANOVA) and comparison of means was carried out according to Turkey's test at the 5% threshold.

3. Results

3.1. Basic identity of Edible Mushrooms

Three (03) mushrooms species were presumptively identified as commonly consumed in Poni province. They include *Agaricus campestris*, *Volvariella volvacea*, and *Cantharellus stramineus* and are described in Table 1.

3.2. Mushrooms Availability

Wild edible mushrooms were collected in the selected communes. Wild edible mushrooms depend on the first rainfall to appear. Their general availability period is ranged from April to November. And, the period of abundant harvest is between June and September, more exactly in July and August. In the past decades, mushrooms were abundantly harvested early in April in this area but today, the first mushrooms are harvested practically in July due to the variation in rainfall in recent years related to climate change. *Agaricus* and *Volvariella* grow from the first rains around June and July while *Cantharellus* is more abundant with the last rains around September and October. Figure 2 show harvesting month rate.

Table 1. Description des champignons comestibles du Poni

Local name	Description	Probable spece
Lobiri : Nàpin kommin Birifor : Nàbiné gourou	Mushrooms with a globular cap, sometimes slightly depressed, with a ring, very fleshy with whitish flesh close to gills. Growing on decomposed organic matter.	<i>Agaricus campestris</i>
Lobiri: kommin bouo Birifor: gourou yirè	Mushrooms with a grayish, ovoid cap that is not very fleshy. Growing on dead, decomposed or decomposing wood.	<i>Volvariella volvacea</i>
Lobiri : kommin Birifor : gourou	Champignons à chapeau convexe puis déprimé au centre, la surface est jaune pâle à jaune grisâtre, chair fibreuse, blanche à jaune pâle dans le pied. Il pousse sur les sols gravillonnaires à proximité des dalles latéritiques. Mushrooms with a convex cap then depressed in the center, the surface is pale yellow to grayish yellow, fibrous flesh, white to pale yellow in the foot. It grows on gravelly soils near lateritic slabs.	<i>Cantharellus stramineus</i>

Figure 2. Availability rate of wild edible mushrooms

3.3. Mushrooms Picking and Traditional Uses

Mushroom harvesting is carried out by the entire community without distinction of gender, but it's mainly women who are involved in mushroom picking. Harvesting is carried out in pastures, along river banks, in termite mounds, and around animal enclosures, from June to October, depending on rainfall variations. Mushrooms are harvested whole, from stem to cap. They are handily dug up, then collected in dishes, baskets, bags, etc. The majority of people interviewed consume mushrooms (72%). The harvested mushrooms are mostly intended for home consumption, but a small portion is often sold at marketplaces freshly, dried, or smoked. Mushrooms are prepared in the same way by everyone. Fresh mushrooms are firstly washed and cut. A soup is prepared with available ingredients, including oil, fresh tomato, onion, soumbala, garlic, and salt. Washed mushrooms are then added to this mixture and left on the stove until cooked. The final sauce can be served with millet, sorghum, or corn paste. Dried mushrooms must first be soaked in water for few minutes to rehydrate before adding them to the boiling soup. Mushrooms can also be fried or grilled and accompanied by salt and chili pepper. People who don't consume edible mushrooms cite allergies, lack of appreciation for the taste, and even a lack of knowledge about mushrooms. Some poisonings even happened, as reported by the respondents. Their symptoms include chronic vomiting, stomach aches, and diarrhea. Some even died eating mushrooms. Mycotherapy is not really established among these communities. Over 97% of respondents use mushrooms only for food.

3.4. Communities's Mushroom Preserving Methods

Drying and smoking are the main methods of mushroom preservation. Drying involves firstly washing the freshly harvested mushrooms and exposing them to the sun for a few days. Smoking involves placing mushrooms in a previously washed container and then

placing them over a low-intensity fire several times. Another smoking method that was reported involves placing mushrooms over an oven, below which a fire is lit. Once mushrooms are dried or smoked, they are collected and preserved in bags, sachets, and canaries, and can remain there for more than a year. Preservation does not diminish the organoleptic qualities of mushrooms, as claimed by the respondent.

3.5. Perceived Impact of Climate Change on Mushrooms

The mushroom collectors reported a drastic decline in the quantity of wild edible mushrooms. Surviewed people indicated that places where mushrooms were once found are now devoid of any mushrooms, with some species even disappearing. About 99.6% of respondents stated about a gradual disappearance of mushrooms and issued a warning. Some mushrooms species may be missed in the next generations. About causes, surviewed people included declining rainfall, forests disappearance, mushrooms's host plant species and termite mounds disappearance, artisanal gold mining, and the use of toxic products such as cyanide and pesticides.

3.6. Proximate Composition

The proximate composition of the mushroom species analyzed are displayed in Table II. As shown, moisture contents were between $7.54 \pm 0.09\%$ (*Agaricus campestris*) and $8.48 \pm 0.06\%$ (*Volvariella volvacea*), and the pH value ranged from 6.19 ± 0.00 (*Volvariella volvacea*) to 7.1 ± 0.00 (*Agaricus campestris*). The acidity was from 5.94 ± 0.00 (*Agaricus campestris*) to $49.05 \pm 0.33\text{g acid/100g DM}$ (*Cantharellus stramineus*). The content in lipids varied from 2.25 ± 0.04 (*Volvariella volvacea*) to $2.69 \pm 0.4\text{g/100g}$ (*Agaricus campestris*), while the contents in crude proteins were $23.03 \pm 0.38\%$ (*Agaricus campestris*) to $36.77 \pm 0.3\text{g/100g}$ (*Cantharellus stramineus*), and ash content were ranged between 11.22 ± 0.47 (*Cantharellus stramineus*) and $25.03 \pm 0.27\text{g/100g}$ (*Volvariella volvacea*). The carbohydrate contents varied from 24.797 ± 0.59 (*Agaricus campestris*) to $28.78 \pm 0.7\text{g/100g}$ (*Volvariella volvacea*) and the fibers contents are ranged between 26.39 ± 0.58 (*Volvariella volvacea*) and $46.70 \pm 0.55\text{g/100g}$ (*Agaricus campestris*). Their energy value varied between 213.20 ± 2.75 (*Agaricus campestris*) and 286.83 ± 3.50 (*Cantharellus stramineus*) kcal/100g. Proximate composition is showed in Table 2.

3.7. Vitamins Content

Beta-carotene content was ranged from 0 to $4.260 \pm 0.04\text{mg/100g}$ (*Volvariella volvacea*), while ascorbic acid (Vitamin C) content varied from $0.103 \pm 0.02\text{mg/100g}$ (*Volvariella volvacea*) to $0.256 \pm 0.00\text{mg/100g}$ (*Agaricus campestris*). (Table 3).

Table 2. Proximate composition of wild edible mushrooms (g/100g of DM)

Paramètre	<i>Volvariella volvacea</i>	<i>Cantharellus stramineus</i>	<i>Agaricus campestris</i>
Moisture (g)	8.48 ±0.06 ^c	8.19±0.15 ^b	7.54±0.09 ^a
pH	6.88±0.02 ^b	6.19±0.00 ^a	7.10±1.00 ^c
Acidity	37.27±0.45 ^b	49.05±0.33 ^c	5.94±0.008 ^a
Lipids (g)	2.69±0.41 ^a	2.55±0.15 ^a	2.25±0.04 ^a
Proteins (g)	27.12±0.33 ^b	36.77±0.3 ^c	23.03±0.38 ^a
Fibres (g)	26.39±0.58 ^a	30.71±0.95 ^b	46.70±0.55 ^c
Ash (g)	25.03±0.27 ^b	11.22±0.47 ^a	11.33±0.00 ^a
Carbohydrates (g)	28.78±0.7 ^b	28.70±1.23 ^b	24.80±0.59 ^a
Energy (kcal)	250.06±4.45 ^b	286.83±3.50 ^c	213.20±2.75 ^a

Values with different letters in exponential at each column level are significantly different at the 5% threshold (Tukey test).

Table 3. Beta caroten and ascorbic acid content of wild edible mushrooms

Speces	Beta-carotene (mg/100g MS)	Vitamin C (mg/100g)
<i>Volvariella volvacea</i>	4.26±0.04 ^b	0.10±0.02 ^a
<i>Cantharellus stramineus</i>	0.00 ^a	0.13±0.04 ^b
<i>Agaricus campestris</i>	0.00 ^a	0.26±0.00 ^c

Values with different letters in exponential at each column level are significantly different at the 5% threshold (Tukey test).

Table 4. Minerals content of the mushrooms species

Speces	K	Mg	Na	Ca	Zn	Fe	Mn	Cu
<i>Cantharellus stramineus</i>	1756.44	187.09	20.5	19.28	3.97	2.92	1.78	1.14
<i>Volvariella volvacea</i>	2830.23	194.03	49.2	195.94	4.86	13.96	5.95	3.89
<i>Agaricus campestris</i>	1476	46.93	32.8	43.16	4.81	14.29	1.82	3.19

3.8. Minerals Content

Table 4 displays the minerals composition in the analyzed mushroom samples. Potassium content varied from 1476 (*Agaricus campestris*) to 2830 (*Volvariella volvacea*), magnesium content from 46.93 (*Agaricus campestris*) to 194.03 (*Volvariella volvacea*) and sodium content was ranged between 20.5 (*Cantharellus stramineus*) and 49.2 (*Volvariella volvacea*). Calcium content varied from 19.28 (*Cantharellus stramineus*) to 195.94 (*Volvariella volvacea*), zinc content from 3.97 (*Cantharellus stramineus*) to 4.86 (*Volvariella volvacea*), iron content from 2.92 (*Cantharellus stramineus*) to 14.29 (*Volvariella volvacea*). Manganese content was ranged from 1.78 (*Cantharellus stramineus*) to 9.95 (*Volvariella volvacea*) while copper content varied from 1.14 (*Cantharellus stramineus*) to 3.89 (*Volvariella volvacea*).

4. Discussion

Three commons mushrooms species of southwest region of Burkina Faso including *Volvariella volvacea*, *Agaricus campestris* and *Cantharellus stramineus* have been used for centuries by communities. Mushrooms are not cultivated and harvesting period is ranged between June and September. Mushrooms is mainly used in households and smoking and drying are the main preserving methods. Human activity and climate change are the main threats to wild edible mushrooms's disappearance. These mushrooms species have an appreciated nutritional value including proximate compounds, mineral content and vitamins.

Burkina Faso in general and Southwest region in particular have a high diversity of wild edible mushrooms [31]. [18] identified about 31 species of edible mushrooms

in Burkina Faso, divided into 14 families and 19 genera, and indicated similar harvesting period. But in the southwest region, mushrooms slightly appear earlier, in avril than in the national scale. [32] also emphasizing that the abundance of precipitation at the local scale would be an indicator of mushrooms's diversity, supporting jully and august as abundant month of mushrooms collection. The decline in mushrooms populations was also put in evidence by [33]. Climate change and human activities are the main factors contributing to the decline of mushrooms, which calls for emergency project for their safeguarding. wild mushrooms have been used mainly as food. This mainly food uses of wild edible mushrooms has been also fund in Côte d'Ivoire [34]. It's a sweetable substitute to meat in many communities [9]. Human activities is a risk factor for non-timber forest products food security and wild edible mushrooms in particular. Several studies put in evidence chemical contaminants of wild edible mushrooms [35,36,37].

In the present study, the sampled common wild edible mushrooms from southwest Burkina Faso showed interesting nutritional values. The variation in the chemical property (moisture content, pH and acidity) may be related to postharvest process and storage conditions. Previous studies also demonstrated non-significant difference in lipids content between *Volvariella volvacea* (2.4%) and *Agaricus campestris* (1.9%) [38]. The content in fibers is in the same order as reported by [39]. The protein contents were in the same order as found by [40,41]. Previous studies showed that proximate content of wild edible mushrooms depends on substrates, species, harvesting period [42].

Studied mushroom species have shown important micronutrient contents. Postharvest processing may have an impact on both beta caroten and ascorbic acid content found in the present study, as the collected mushrooms are

dried to prevent alteration. Previous studies [43,44] revealed appreciable content of ascorbic acid and beta caroten content in mushrooms including the same species? but below FAO recommendation. [45] have already demonstrated mushrooms have high level content in minerals due to their capacity in accumulating minerals. But soil contamination could also explain the high level of minerals content. [46] also fund K, Ca and Mg as the most abundant minerals in mushrooms. The important minerals content (Fe, Zn, Ca...) in mushrooms make it a potential source for under five years children food formulation, as anemia is more associated to children malnutrition. Wild edible mushrooms have appreciated nutritional value, but only available during raining season. As they are treathened by both climate change and human activities, mushrooms domestication and cultivation is the appropriate solution for their safeguarding.

5. Conclusion

Common wild edible mushrooms in South-west Burkina Faso included *Volvariella volvacea*, *Cantharellus stramineus* and *Agaricus campestris*. Their abundance and availability depend on rainfall. They are appreciated meals for indigenous communities in Southwestern Burkina Faso but climate and human activities threatening they survival. As shown, they may have high nutritional value, requiring initiatives to safeguard them, either creating biobank or through domestication and demonstrating their detailed nutritional values and safety/
